

# WHAT IS IT?

- The DOM is a JavaScript representation of a webpage.
- It's your JS "window" into the contents of a webpage
- It's just a bunch of objects that you can interact with via JS.

```

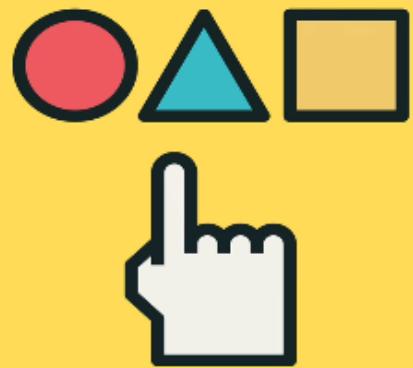

> document
< - #document
  <!DOCTYPE html>
  <html dir="ltr" lang="en" class="focus-outline-visible">
    > <head>...</head>
    > <body style="background-color: rgb(255, 255, 255);">...</body>
  </html>
> console.dir(document)

  - #document ⓘ
    URL: "chrome://new-tab-page/"
    > activeElement: body
    > adoptedStyleSheets: []
    alinkColor: ""
    > all: HTMLAllCollection(144) [html.focus-outline-visible, head, meta, title, style, custom-style]
    > anchors: HTMLCollection []
    > applets: HTMLCollection []
    baseURI: "chrome://new-tab-page/"
    bgColor: ""

```

# SELECTING

- getElementById
- getElementsByTagName
- getElementsByClassName

Like

document

>>> gives u the html

so u have to do

console.dir(document)

>>> to get the object

Likewise

whenever you use select elements using Dom, you have to use console.dir to view the object.

It's iterable but it's not an array so u can't use map, reduce..

# querySelector

- A newer, all-in-one method to select a single element.

```
//Finds first h1 element:  
document.querySelector('h1');  
  
//Finds first element with ID of red:  
document.querySelector('#red');  
  
//Finds first element with class of  
document.querySelector('.big');
```

In query selector, we pass the “sameway of selector we pass in Css”  
queryselector only selects one elements and return.

# querySelectorAll

Same idea , but returns a collection of matching elements

innerHTML , textContent & InnerText

## PROPERTIES & METHODS

(the important ones)

- classList
- getAttribute()
- setAttribute()
- appendChild()
- append()
- prepend()
- removeChild()
- remove()
- createElement

- innerText
- textContent
- innerHTML
- value
- parentElement
- children
- nextSibling
- previousSibling
- style

textContent: is gonna look like the how u written your html content.even though any <span> is display:none , You can see in the textContent.  
So every piece of content is gonna show.

innerHTML:what you see on the browser exactly like that. It is sensitive to what is showing on the moment .

e.g

```
const x=document.querySelector("nav a");
x.innerText=<b> mumbai_foodbasket </b>
            <!-- this will not work, it will consider b tag as string.
```

//so use

```
x.innerHTML=<b> mumbai_foodbasket </b>"
```

innerHTML

smart

textContent

better

innerText

compact

draw as written in .html  
Not dumb, sensitive to  
what is currently shown.

dumb

## Attributes

```
const firstlink=document.querySelector("a").src
firstlink.setAttribute('href','https://www.udemy.com/course/the-web-
developer-bootcamp/learn/lecture/22003782#overview')
```

```
- document.querySelector('a').title
- "List of chicken breeds"
- const firstLink = document.querySelector('a')
- undefined
- firstLink.href
- "file:///wiki/List_of_chicken_breeds"
- firstLink.getAttribute('href')
- "/wiki>List_of_chicken_breeds"
-
```

when you use `getAttribute()` you are getting directly from the html itself.  
& when you access property directly on the element like “`.href`” i.e is going through js. So we can see we got different value.

## Styles

selected element object has a property i.e style

h1.style <!-- In Css we have background-color, but in the style object  
we dont have “-”. Instead its camelcase  
i.e backgroundColor

h1.style <!-- only stores inline style, not from our stylesheet

Here, you whatever you do would be inline style, you should avoid using inline style.

i.e h1.style.color=blue;

-Better way to apply styles to elements is to use a class

Issues with style property:

-inlines are bad

-using style property you can only see style attribute.

So unless you wrote the style inline, you can't read the style. I cant tell what is the `fontSize` of the element...

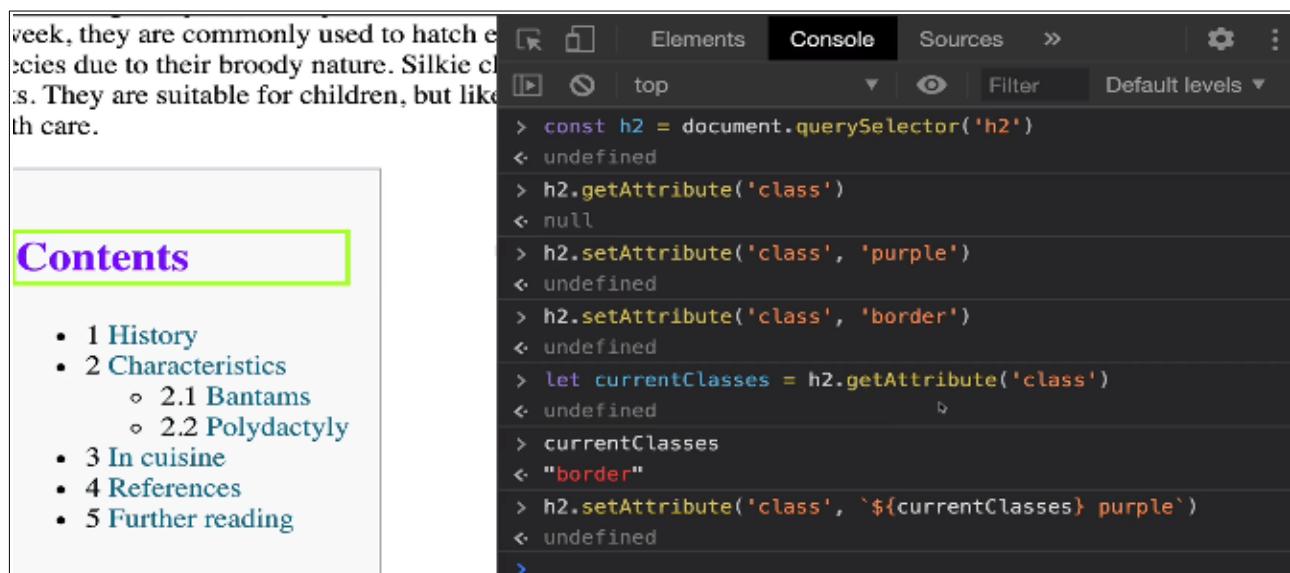

So what if i wanna make something the same font-size idk how big it is, atleast by not looking at my css

So there is another way. To find the actual computed style once everything is applied. It's not as easy just to look at your .css copying the style over. Because you can have multiple stylesheet n they may have conflicting sytles and specificity.

-You have to wait until everything is loaded and computed to figure out actual style.you can do by using

`window.getComputedStyle(h1).fontSize`

This is not a query selector, this is the actual element object in dom

A screenshot of a browser's developer tools console. The console tab is active. The code shown is:

```
> const h2 = document.querySelector('h2')
< undefined
> h2.getAttribute('class')
< null
> h2.setAttribute('class', 'purple')
< undefined
> h2.setAttribute('class', 'border')
< undefined
> let currentClasses = h2.getAttribute('class')
< undefined
> currentClasses
< "border"
> h2.setAttribute('class', `${currentClasses} purple`)
< undefined
>
```

The left side of the image shows a portion of a web page with a sidebar containing a "Contents" section with a list of links:

- 1 History
- 2 Characteristics
  - 2.1 Bantams
  - 2.2 Polydactyl
- 3 In cuisine
- 4 References
- 5 Further reading

a week, they are commonly used to species due to their broody nature. S pets. They are suitable for children, with care.

## Contents

- 1 History
- 2 Characteristics
  - 2.1 Bantams
  - 2.2 Polydactyl
- 3 In cuisine
- 4 References
- 5 Further reading

## History

```
Elements  Console  Sources  »  ⚙  ⋮
top  Filter  Default levels ▾

> const h2 = document.querySelector('h2')
< undefined
> h2.classList
< > DOMTokenList [value: ""]
> h2.classList
< > DOMTokenList [value: ""]
> h2.classList.add('purple')
< undefined
> h2.classList.add('border')
< undefined
> h2.classList.remove('border')
< undefined
> h2.classList.contains('border')
< false
> h2.classList.contains('purple')
< true
> |
```

```
h2.classList.toggle('purple')
true
```

It might seem easier to change style using style property but by classlist its much more simple where you can apply bunch of property by adding class or multiple classes. You can also remove class and toggle.

## Traversing parent/child/sibling

i.e

parentElement

Children

nextElementSibling

previousElementSibling

Last child

LastElementChild

NextSibling

All this property allows us to navigate, traverse, move from one element to some relative or to its parent or to its parent parent.

```
> firstBold.parentElement
:  ► <p>...</p>
> firstBold.parentElement.parentElement
:  ► <body>...</body>
> firstBold.parentElement.parentElement.parentElement
:  <html lang="en">
:    ► <head>...</head>
:    ► <body>...</body>
:   </html>
> const paragraph = firstBold.parentElement
: undefined
> paragraph.children
:  ► HTMLCollection(8) [b, b, a, a, a, a, a, a]
> paragraph.children[0]
:  <b>Silkie</b>
> paragraph.children[0].parentElement
:  ► <p>...</p>
```

nextSibling and previousSibling is gonna give us a node.

For e.g inside <h1>...</h1> we have a text node.

Some browser make new lines a text node.

is unknown exactly where or when these fowl with their singular combination of attributes first appeared, but the most well documented nest of origin is ancient China (since another occasionally encountered name for the bird, Chinese silk chicken). Other places in Southeast Asia have been named as possibilities, such as India and Java.<sup>[2]</sup> The earliest surviving written account of Silkies comes from Marco Polo, who wrote a "furry chicken" in the 13th century during his travels in Asia.<sup>[3]</sup> In 1996, Ulisse Alberoni, a writer and naturalist at the University of Padova, Italy, published a comprehensive monograph on chickens which is still read and cited today. In it, he spoke on "woolly breeding chickens" or ones "clothed with hair like that of a black cat".<sup>[4]</sup>

[Silky\\_bantam.jpg](#)" alt>

```
> squareImg.nextSibling
<  ► #text
> squareImg.nextSibling
<  ► #text
> squareImg.previousSibling
<  ► #text
> squareImg.nextElementSibling
<  
> squareImg.previousElementSibling
<  ► <p>...</p>
```

## createElement

```
const newImg=document.createElement('img')
console.dir('newImg')      <!--to view
newImg.src="
```

```
const newH3 = document.createElement('h3')
undefined
newH3
<h3></h3>
newH3.innerText = 'I am new!'
'I am new!'
document.body.appendChild(newH3)
<h3>I am new!</h3>
```

## appendChild

---

```
> const p = document.querySelector('p')
<- undefined
> p.append('i am new text yaaaaaayyy!!!')
<- undefined
> p.appendChild('i am new text yaaaaaayyy!!!')
✖ > Uncaught TypeError: Failed to execute VM17493:1
  'appendChild' on 'Node': parameter 1 is not of
    type 'Node'.
    at <anonymous>:1:3
>
```

```
p.append('i am new text yaaaaaayyy!!!',
'asdasdasdasdasdasd')
```

It allow us to insert more than one thing at a time

```
const newB = document.createElement('b')
undefined
newB.append('Hi!')
undefined
newB
<b>Hi!</b>
p.prepend(newB)
undefined
```

```
y.append(div1,div2)
```

## Element.insertAdjacentElement [click](#)

### Parameters

#### position

A `DOMString` representing the position relative to the `element`; must be one of the following strings:

- `'beforebegin'`: Before the `element` itself.
- `'afterbegin'`: Just inside the `element`, before its first child.
- `'beforeend'`: Just inside the `element`, after its last child.
- `'afterend'`: After the `element` itself.

```
> const h2 = document.createElement('h2')
<- undefined
> h2.append("Are adorable chickens")
<- undefined
> h2
<- <h2>Are adorable chickens</h2>
> const h1 = document.querySelector('h1')
<- undefined
> h1.insertAdjacentElement('afterend', h2)
<- <h2>Are adorable chickens</h2>
> h1.nextElementSibling
<- <h2>Are, adorable chickens</h2>
```

```
const h3 = document.createElement('h3')
undefined
h3.innerText = 'I am h3';
"I am h3"
h1.after(h3)
undefined
```

```
const firstLi = document.querySelector('li')
undefined
firstLi
▶<li class="toclevel-1 tocsection-1">...</li>
const ul = firstLi.parentElement
undefined
ul
▶<ul>...</ul>
ul.removeChild(firstLi)
▶<li class="toclevel-1 tocsection-1">...</li>
|
```

Another way

```
firstLi.parentElement.removeChild(firstLi)
<!-- This works but isn't considered best practice
```

Another way

```
const img = document.querySelector('img')
undefined
img.remove()
undefined
```

# EVENTS

Responding to  
user inputs  
and actions!

## A SMALL TASTE

- clicks
- drags
- drops
- hovers
- scrolls
- form submission
- key presses
- focus/blur

- mouse wheel
- double click
- copying
- pasting
- audio start
- screen resize
- printing

Inline event

for e.g

```
<button onclick="alert('you clicked a button')">click Me </button>
```

If you wanna write multiple lines in you have to make seperation using “;”

i.e

for double click

just like in linux cmd

```
<button ondblclick="alert('you clicked a button') ;alert('stop clicking me')">click Me </button>
```

```

  accessKey: ""
  ariaAtomic: null
  ariaAutoComplete: null
  ariaBrailleLabel: null
  ariaBrailleRoleDescription: null
```

So basically dom objects have properties for e.g onclick or onmouseenter we can assign a function to it, so whenever there is a click or mouseenter it will run that function

A very important note

Set of do and donts

```
mydiv1.onclick=alert("hello there sahil");
```

this isn't equivalent to

```
mydiv1.onclick=function(){
|   alert("hello there kazim")
|}
```

Your properties should be given a proper function.

The mistake is that it will run the function right away.

Whereas the below one.

We are setting a property to a function. It should refer to a func.

```

btn.onclick = function () {
    console.log("YOU CLICKED ME!")
    console.log("I HOPE IT WORKED!!")
}

function scream() {
    console.log("AAAAAHHHHH");
    console.log("STOP TOUCHING ME!")
}

btn.onmouseenter = scream;

```

See Above, you're passing the function on the event but you aren't executing.

## addEventListener

Specify the event type and a callback to run

```

const button = document.querySelector('h1');

button.addEventListener('click', () => {
    alert("You clicked me!!")
})

```

Not all events work on every element. For e.g keypress doesn't work on a button.

You wanna use addEventListener over onclick/..... cuz you can't have two callback functions on the same event for e.g click.

mybtn.onclick=sayMyName;      Doesn't work

mybtn.onclick=sayMyNickName; X only listen for last event

-----

mybtn.addEventListener('click',sayMyName)

mybtn.addEventListener('click',sayMyNickName)

✓ Here,  
both events are  
listening

```

tasButton.addEventListener('click', twist, { once: true })
tasButton.addEventListener('click', shout)

```

Tip: when you set property

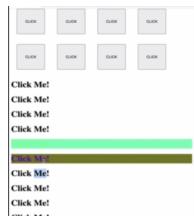

document.body.backgroundColor='rgb(200,255,300)'; <!-- key:value(str)

## Events and the keyword this(Important 3stars)

I think we are not giving enough credit to this.

Summary:The keyword this with a callback

Aim:

Reasoning: Basically on click events we want the text and the background-color to change.

We were having the same code written twice. So we used a function.

A function when passed into like an argument is a callback.

The Keyword this in this function aka callback refers to the dom object on which the event was fired.

```
const buttons = document.querySelectorAll('button');

for (let button of buttons) {
  button.addEventListener('click', function () {
    button.style.backgroundColor = makeRandColor();
  })
}
```

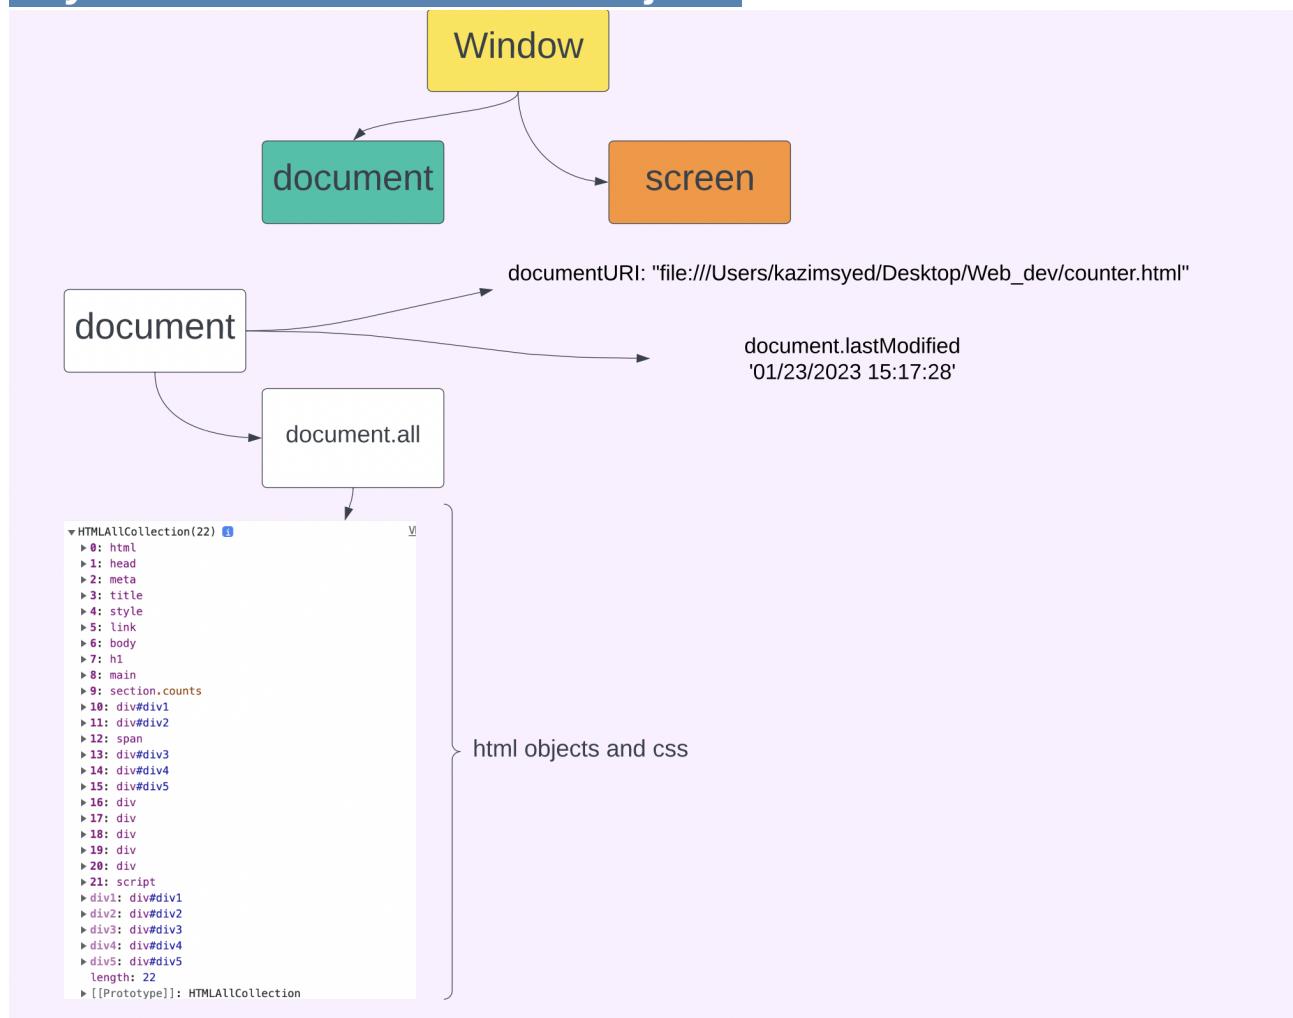

```
for (let button of buttons) {
  button.addEventListener('click', colorize)
}

const h1s = document.querySelectorAll('h1');
for (let h1 of h1s) {
  h1.addEventListener('click', colorize)
}

function colorize() {
  this.style.backgroundColor = makeRandColor();
  this.style.color = makeRandColor();
}
```

The keyword 'this' when You have it inside a callback ,that is invoked by some event handler, 'this' refers to the element the eventlistener was listening.

## Keyboard Events and Event Objects

main > Section.counts

```
TagName:"SECTION"
ParentNode:main
ChildNodes:NodeList(11) [ text, div, text, div, text, div, text, div,
text,...]
Children:HTMLCollection(5)[div,div,div,div,div]
firstChild:text
firstElementChild:div
classList > className:"counts"
previousElementSibling:null
previousSibling:null
lastChild:text
lastElementChild:Div
.attributes.length
.attributes['class'].nodeName
.innerHTML() : just gives me the the html with the
content. Boring
.innertext() : gives me only the text that is visible to the
user within the tags. Amazing+Compact

textContent(): gives me the text within the tags

style
```

main > Section.counts>div

```
TagName:"DIV" style
ParentNode:section.counts
ChildNodes:NodeList(1) [ text]
Children:HTMLCollection()
firstChild:my name is sahil1
firstElementChild:"

classList > className:""
previousElementSibling:null nextElementSibling:div
previousSibling:text previousSibling:text
.attributes.length :2
.attributes['data-tool-tip'].nodeName
.attributes['id'].nodeName
e.attributes['data-tool-tip'].nodeValue
'my name is sahil1'

.innerHTML() : just gives me the the html with the
content. Boring
.innertext() : gives me only the text that is visible to the
user within the tags. Amazing+Compact
textContent(): gives me the text within the tags
```

diff between KeyUp and  
KeyDown

In the case of KeyUP, if u hold the key down for a while and then release for e.g backspace. It will fire only one event for KeyUp. But for the case of keydown, if i am holding backspace, it will register backspaces. Imagine i wanna delete the entire line at my cursor is at the end. so i would hold it.

Similarities for KeyUp and  
KeyDown

Keyboard events are only generated by <input>, <textarea>, <summary> and anything with the contentEditable or tabindex attribute.

Keyboard events

They can be fired for like input[type='text'] when im hitting the down array key. There isn't any change in the input. But the event is getting triggered.

```
> document.addEventListener('keydown', (e)=>{
    console.log(e.code,e.key)
});
<- undefined
KeyA a
KeyB b
CapsLock CapsLock
ShiftLeft Shift
```

Figure 1: e.code , e.key

what i am writing is the  
key and the code is the  
codified name

keyboard  
events(e.code,e.key)

If u change ur language settings, so where your is w,a,s,d or u may not even have those letters aka key but u care about the position of w,a,s,d for ur game. So use code.

But if i use 'code' it doesn't matter. So if we care about position on keyboard use 'code'. But what you care about is the 'char', use 'key'. For e.g -y for yes and its a weird keyboard.

Again, if you dont care which button you pressed to generate the char use 'key' then.

## Keyloggers

Use window.Eventlistener()

```
window.addEventListener('keydown', function (e) {
  switch (e.code) {
    case 'ArrowUp':
      console.log("UP!");
      break;
    case 'ArrowDown':
      console.log("DOWN!");
      break;
    case 'ArrowLeft':
      console.log("LEFT!");
      break;
    case 'ArrowRight':
      console.log("RIGHT!");
      break;
    default:
      console.log("IGNORED!")
  }
})
```

```
input.addEventListener('keydown', function (e) {
  console.log("KEYDOWN")
```

```
▼ KeyboardEvent {isTrusted: true, key: "q", code:  
"KeyQ", location: 0, ctrlKey: false, ...} ⓘ
```

key: "q"

charCode: 0

code: "KeyQ"

a	Key	Shift	Key
KeyA	Code		
		ShiftLeft	Code
Space	code		

Enter ur name		Description	syed	Enter
---------------	--	-------------	------	-------

Attributes: {0:action,1:id}  
Autocomplete:"on"  
Autofocus:false  
ChildNodes:Nodelist(11)  
Children:HTMLCollection(5)  
childrenElementCount

contentEditable:inherit  
Draggable:false  
Name:””  
nextSibling  
nextElementSibling  
nodeValue  
previousSibling  
Parent node:SECTION  
Parent Element:sECTION

firstChild:text  
firstElementChild:label  
STYLE  
lastChild:text  
lastElementChild  
**Elements**  
0:input id input\_1  
1:input id input \_dEsc  
2: button  
tagName:Form

So u have to refer through indexing like form\_obj.elements[0].  
SO what if, u change the order. The code will break.

Tip:

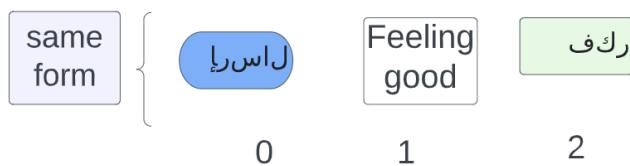

To get the value that user entered

```
form_obj.elements['1']
```

But what if we wanna change the order?

It works cause its in the center. but we can't be sure of that always and most likely our code will break.

if u put the name attributel= like form > input[type='text' name="txt\_thoughts"] you can access this variable using **form.elements.txt\_thoughts.value** just like an object's field.

we pass the value from the form in the form of an object.

?name=kazim&age=22.

```
<form action="/dogs">
  <input type="text" name="username" placeholder="username">
  <input type="text" name="tweet" placeholder="tweet">
  <button>Post</button>
</form>
```

```
const tweetForm = document.querySelector('#tweetForm')
tweetForm.addEventListener('submit', function (e) {
  console.log("SUBMIT!!")
  e.preventDefault();
});
```

if action isn't specified it will send data to the page you are on rightnow.

In below, put `e.preventDefault()` afterbegin inside eventlistener.

```
const tweetForm = document.querySelector('#tweetForm');
tweetForm.addEventListener('submit', function (e) {
  // const usernameInput = document.querySelectorAll('input')[0];
  // const tweetInput = document.querySelectorAll('input')[1];
  const userbane = tweetForm.elements.username.value;
  const tweet = tweetForm.elements.tweet.value;
  |
  // console.log("SUBMIT!!")
  e.preventDefault();
});
```

Tip: The form is submitted by pressing 'Enter' not just by clicking the Submit button.

## Input & Change events

---

There is copy/paste using mouse Or voice over utility, so there are different ways of updating a input and keydownkeyup doesn't encompass all.

## EVENT

**change**:-only fires when you go in and out of input element **that is** only if the input was different before you enter the input.

**input**:-everytime there is a change not just when you go in or out of an input. For e.g: shift or arrow keys wont fire this event. If you cut and paste that will fire this event.

lets say

input[type='text' autofocus=true]

so when the page load this input element will be on focus.

Alright.

Lets say you dont have anything to do with this input.

So u goto the console.

No event is been fired.

But lets say u type ur name and get out of the element. You havent pressed enter. It will still fire.

Cause there is a change.

**that is** only if the input was different from what it was before you enter the input.

Lets say

input[type='focus' autofocus value='kazim']

lets you backspace d and then type d without leaving the box focus mode.

So its still kazim

and u went out of it.

The input will not fire.

So if u want the event to be fired

if there is a change and even if u didnt left the focus mode.

Use input

\*\* a live preview.

when if u want the event to be fired

when you get out of the focus mode and it checks whether there is a change.

If it is it will fire, then use change mode.

\*\* wont be able to achieve live preview cuz ill have to leave the tab.

--

you have to use this. Cause keydown won't work with copy and pasting using mouse.

Keydown and keyup will trigger for every key that is pressed.

## Event bubbling

---

```
<body>
  <section onclick="alert('section clicked')">
    <p onclick="alert('paragraph clicked')">
      I am a paragraph:
      <button onclick="alert('button clicked')">Click</button>
    </p>
  </section>
```

Above, button triggered > para triggered > section triggered.

-Use `e.stopPropagation()`;

--

Another e.g

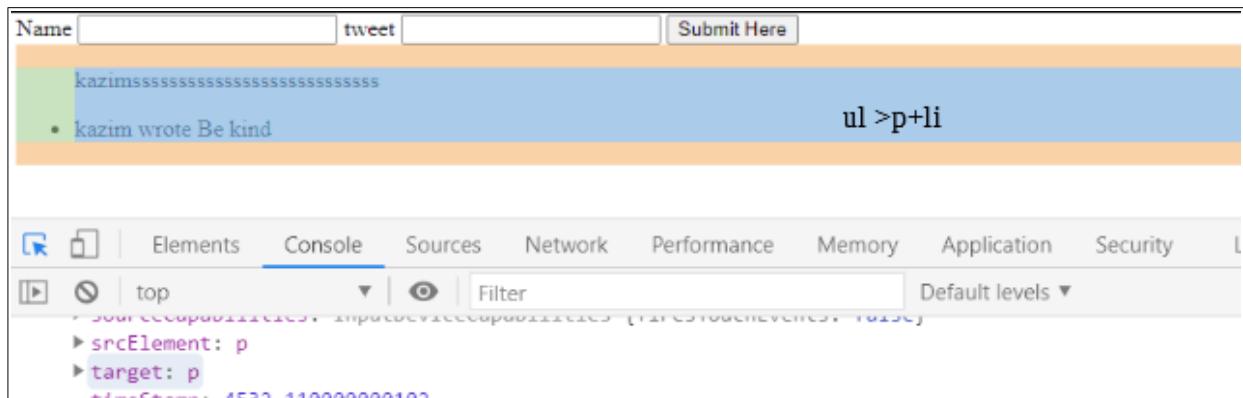

Click To Hide

div > btn.onclick(giveRandomColor)

```
div.addEventListener('click',(e)=>{
  div.classList.toggle('hiding')
})
```

So if i click on btn nested in the div, the div will dissapear. This is event bubbling.

## Event Delegation

Above, on li we have listener which on click are removed. But above if we submit and create a new li, it will not have a listener. So here, we placing a listener on ul.

It means we gonna add event listener to some element that is a parent. Here, We gonna listen click on ul but specifically on li that is in ul. So even though i have eventListener on ul, but the target is p here.

```
myul.addEventListener("click", (e) =>{
  e.target.nodeName === 'LI' && e.target.remove();
});
```

## Working with select

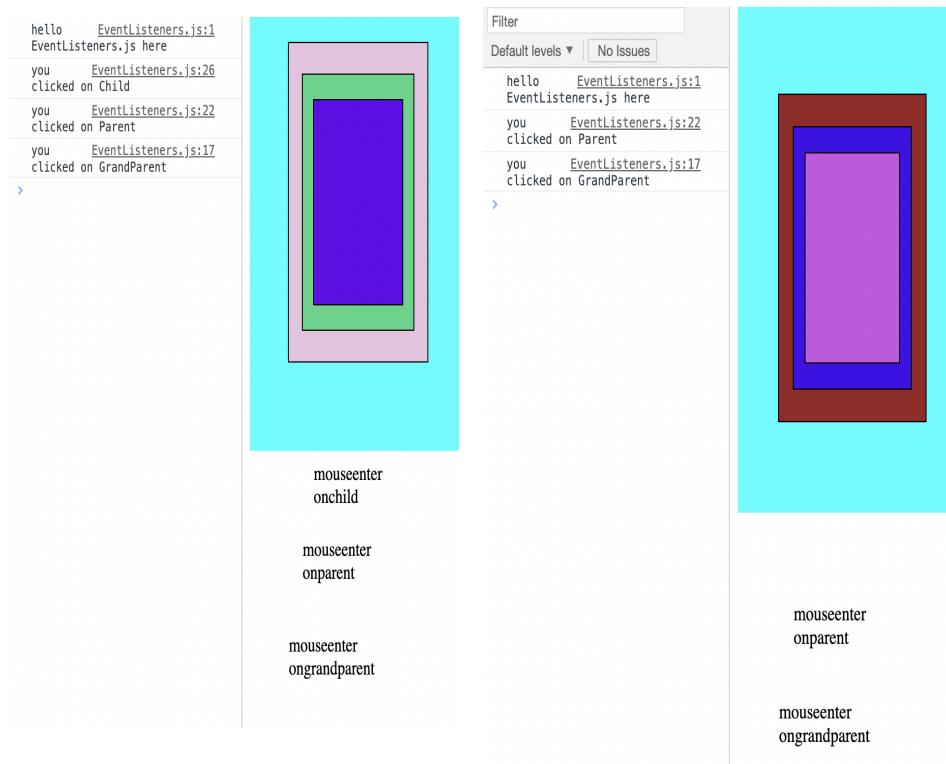

```
myselect.addEventListener("change", function(){
  // console.dir(e.target.options.selectedIndex);
  // max=e.target[e.target.options.selectedIndex].value;
  max=this.value;
  console.dir(this);
});
```

## AddEventListener options:

The "capture" option in `addEventListener` is a boolean value that specifies the phase of event propagation to listen for the event.

- If the capture value is set to `false` (default), the event listener will be triggered during the bubbling phase, i.e., it will be called when the event has propagated from the target to the top of the DOM tree.
- If the capture value is set to `true`, the event listener will be triggered during the capturing phase, i.e., it will be called when the event is first captured and travels down the DOM tree towards the target.

It allows you to control the order in which event handlers are called, as well as the direction of event flow (from the top of the DOM tree down, or from the target up)

```
x[0].addEventListener('click',(e)=>{
  console.log("you clicked on GrandParent");
});

x[1].addEventListener('click',(e)=>{
  console.log("you clicked on Parent");
});

x[2].addEventListener('click',(e)=>{
  console.log("you clicked on Child");
});
```

This is event bubbling.

Event Capturing using the capture: true option in addEventListener:

The event triggered propagates from top of the dom tree.  
It doesn't mean event bubbling is ignored. They both happened.

More likely it isn't handled cuz the default value for capture: false

The diagram shows three nested div elements: a brown outermost div (GrandParent), a light blue middle div (Parent), and a pink innermost div (Child). To the left of the divs is a vertical log of event logs:

```
hello      EventListeners.js:1
EventListeners.js here
you      EventListeners.js:17
clicked on GrandParent
you      EventListeners.js:26
clicked on Child
you      EventListeners.js:22
clicked on Parent
```

Below the log, three blue arrows point from right to left, indicating the direction of event propagation:

- An arrow pointing to the GrandParent div is labeled "mouseenter onchild".
- An arrow pointing to the Parent div is labeled "mouseenter onparent".
- An arrow pointing to the Child div is labeled "mouseenter ongrandparent".

On the right side of the diagram, the text "So dry running:" is followed by two sets of tags:  
<event capturing>  
<event bubbling>

Below this, the text "Here, since there isn't a code for event bubbling for grandparent. Thats why nothing there." is written.

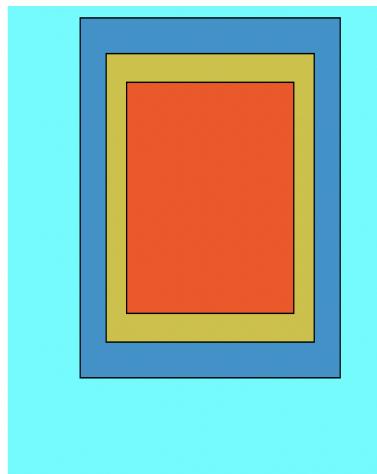

Code:

```
x[0].addEventListener('click',(e)=>{
  console.log("you clicked on GrandParent");
}, {capture: true});

x[1].addEventListener('click',(e)=>{
  console.log("you clicked on Parent");
});

x[2].addEventListener('click',(e)=>{
  console.log("you clicked on Child");
});
```

```
Console has cleared → View Log
↳ undefined
you      EventListeners.js:17
clicked on GrandParent with
event capturing
you      EventListeners.js:31
clicked on Child
you      EventListeners.js:27
clicked on Parent
you      EventListeners.js:22
clicked on GrandParent with
event bubbling
>
```

mouseenter onchild

mouseenter onparent

mouseenter ongrandparent

code:

```
x[0].addEventListener('click',(e)=>{
  console.log("you clicked on GrandParent with event capturing");
}, {capture: true});

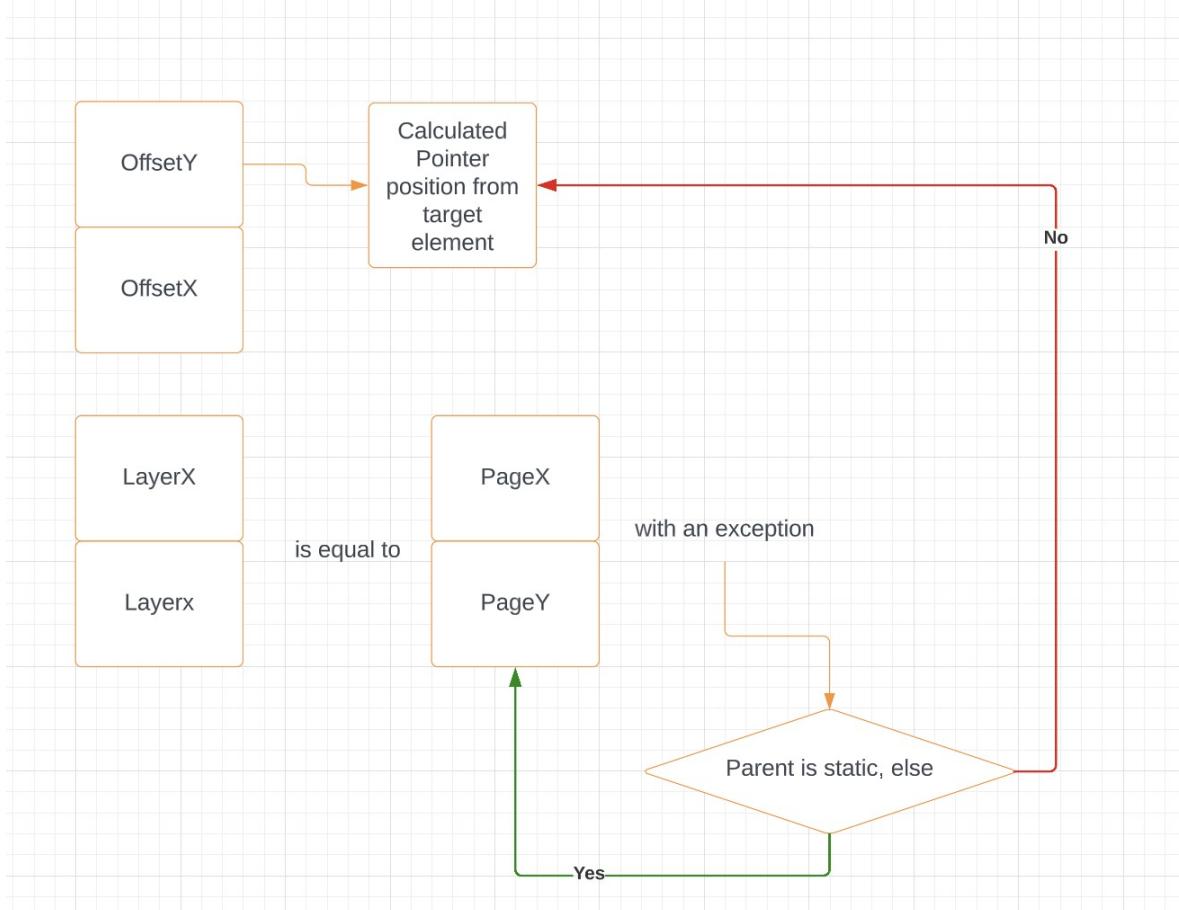

x[0].addEventListener('click',(e)=>{
  console.log("you clicked on GrandParent with event bubbling");
}, {capture: false});
```

for a listener to be called only once.

```
x[0].addEventListener('click',(e)=>{
  console.log("you clicked on GrandParent with event bubbling");
}, {capture: false,once:true});
```

## PointerEvents:

LayerX and LayerY Retrieves the x-coordinate, y-coordinate respectively of the mouse pointer relative to the top-left corner of the closest positioned ancestor element of the element that fires the event.

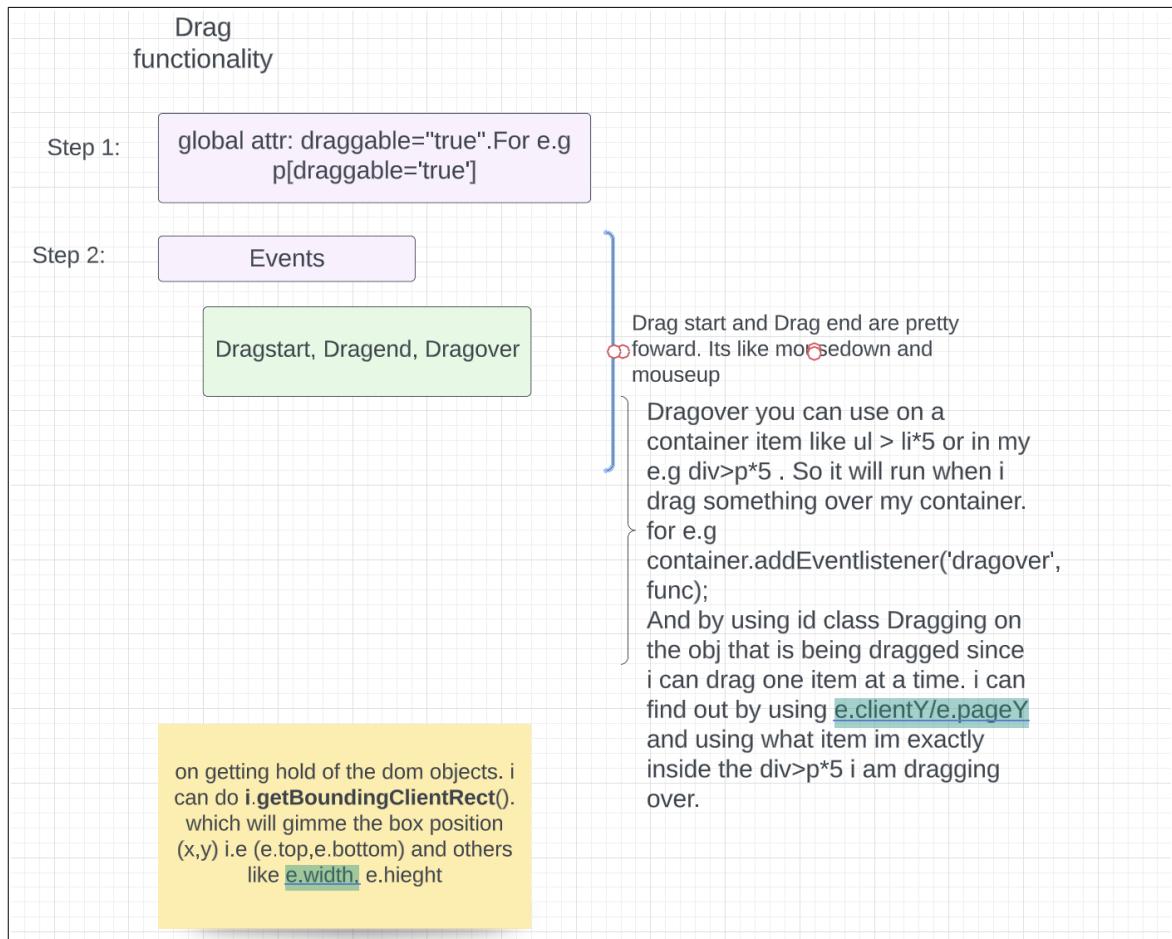

To use the drag functionality.

```
> el=document.getElementsByTagName('h1')
< > HTMLCollection [h1]
> el[0].style.border='1px solid black';
< '1px solid black'
> el[0].getBoundingClientRect().top
< 99.375
> document.addEventListener('click',(e)=>{
    console.log('i am being clicked',e.pageY)
  });
< undefined
i am being clicked 101
>
```

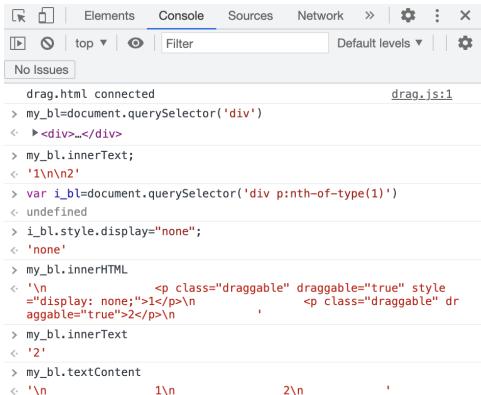

VM1554:2

Figure 2: I clicked right on the border above H

## ***innerHTML vs innerText vs textContent***

```
drag.html connected drag.js:1
> my_bt=document.querySelector('div')
<  ><div>~</div>
> my_bt.innerText;
< '1\n\n2'
> var i_bt=document.querySelector('div p:nth-of-type(1)')
< undefined
> i_bt.style.display="none";
< 'none'
> my_bt.innerHTML
< '\n      <p class="draggable" draggable="true" style
="display: none;">1</p>\n      ,       <p class="draggable" dr
agable="true">2</p>\n'
> my_bt.innerText
< '2'
> my_bt.textContent
< '\n      1\n      2\n      '
```
